Task Document & Evaluation Guide: Students Registration Forms

(Usage of AI tools are strictly prohibited)

Student Signup Form: A clean form collecting Name, Email, Password, Date of Birth, Gender (radio buttons), Qualification (dropdown), Interests (checkboxes), Class, Subject, Marks, and an Aadhaar document upload.

- Validation: If an email already exists in the database, stop them and show this exact error: "This email is already registered."
- File validation: must be pdf
- Automatically rename uploaded Aadhaar files on the server so multiple users uploading files with the same name never overwrite each other.

Single Login Form: A unified login screen for both admins and students.

- *Redirection:* Logging in with the admin email routes to the Admin Dashboard; student emails route to their Student Dashboard. Include a functional Forgot Password link/flow.

Admin Dashboard (Protected): Accessible only via the admin login.

- Displays a table of all registered students
- Filters instantly by Name and Class.
- Filter by Age (minimum) and (maximum)
- Includes clickable links to open uploaded Aadhaar files.

- Provides CRUD controls: Delete records, and Edit user details (**Name and Email must stay locked/uneditable**).

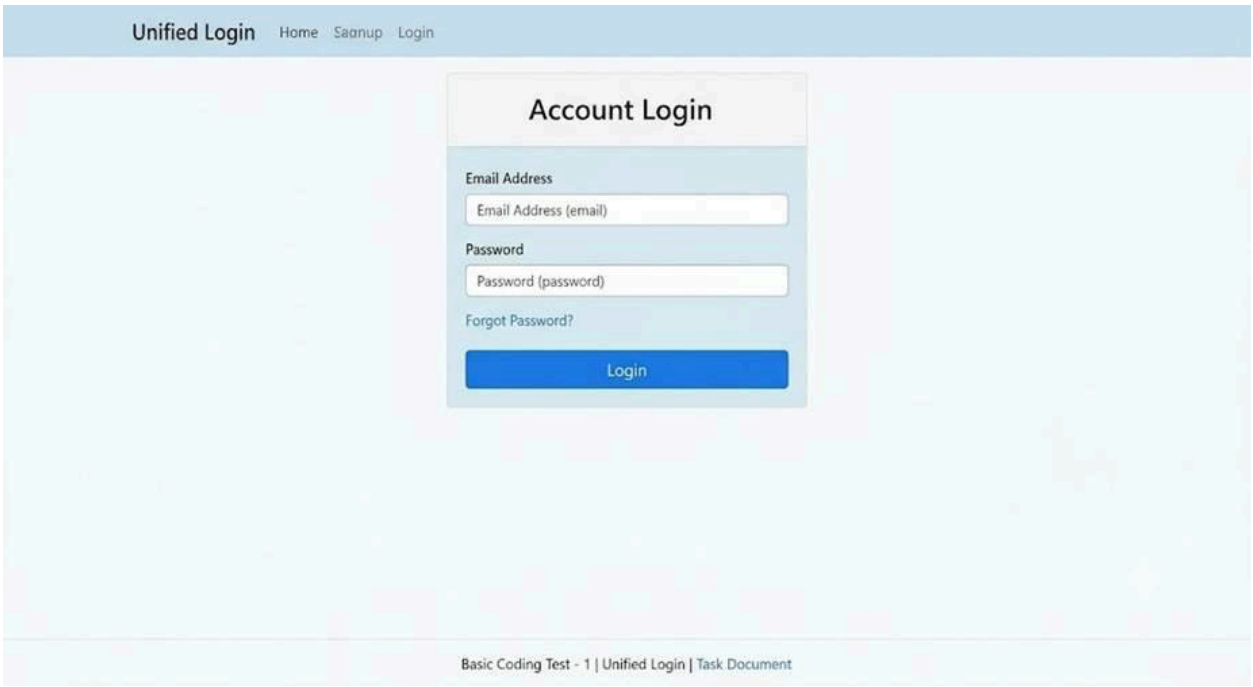

Student Dashboard & Profile Editing:

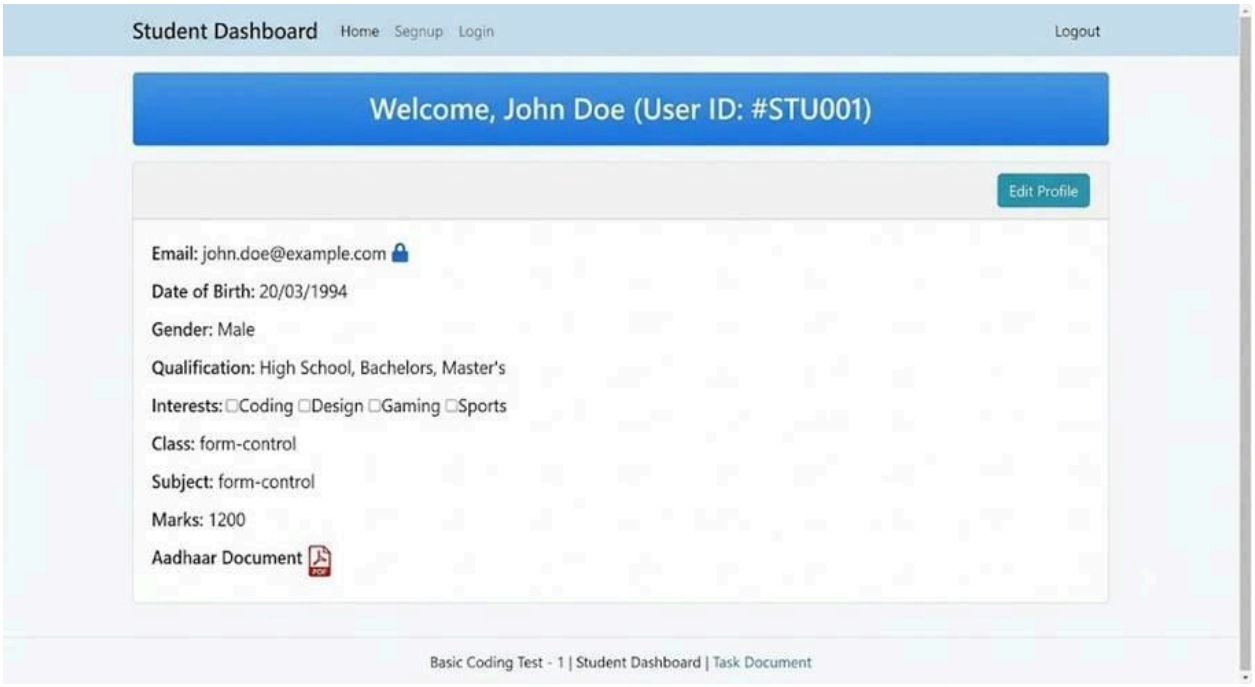

- Displays a welcome banner: "Welcome, [User Name] (User ID: #[ID])" along with all submitted details.
- Includes an "Edit Profile" button to update info (excluding email) and replace the Aadhaar document.

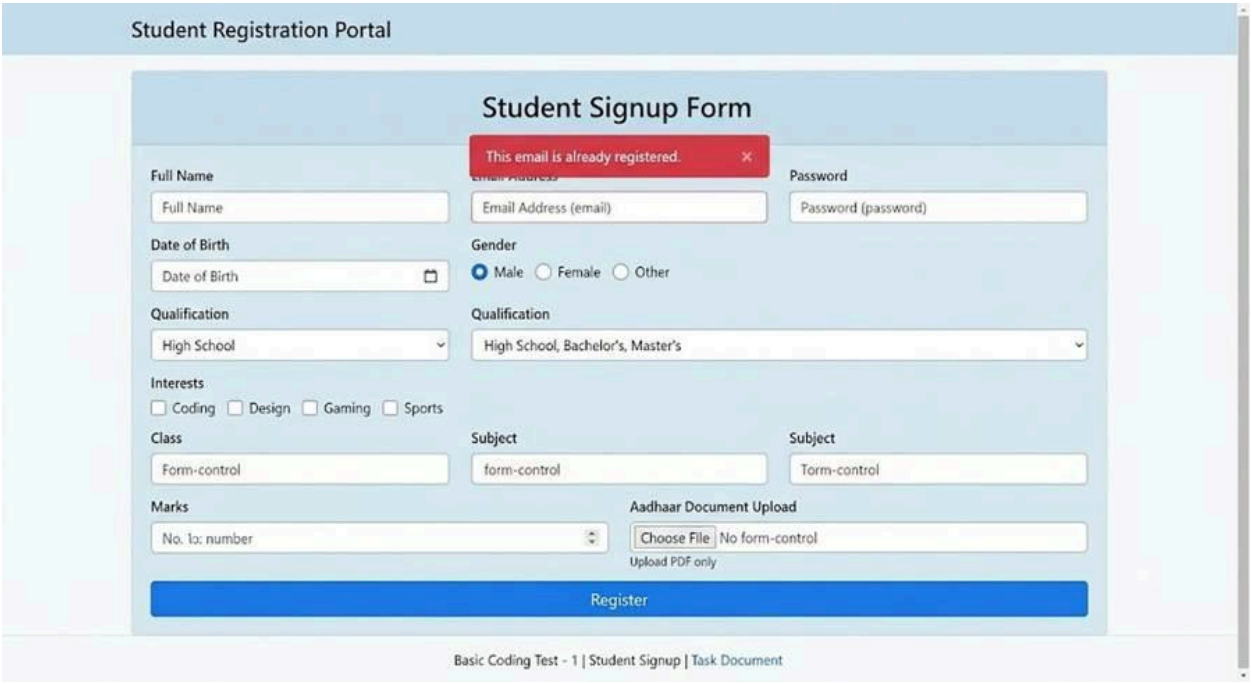

Must Include:

- CRUD operations — Create, Read, Update, Delete.
- Use one backend, one frontend, one database — connect it all.
- Use PHP + MySQL or Any backend(Django/NodeJS/Springboot)
- Design clean pages using HTML, CSS, Bootstrap , keep it neat and simple.

Fallback Implementation Note: If the PHP/MySQL backend is unavailable or encounters critical issues during the test, implement a frontend-only simulation using JavaScript. Utilize localStorage or JSON array objects as a mock database to persistently store user records across sessions. This client-side approach must seamlessly execute the entire user flow—including duplicate email validation, conditional login redirection, admin CRUD operations, and student profile updates—ensuring the application functions exactly as it would with a live server.

SCREENING ROUND 1

3 -Hour Practical Technical Assessment

Evaluation & Observation Points

Registration & Input Handling: Check if all required fields are present and styled properly. Verify that entering an existing email triggers the exact required error message ("This email is already registered.") and that login/forgot password flows work.

File Upload Security: Inspect the server upload directory to confirm uploaded Aadhaar files are saved with unique randomized names instead of original filenames. Verify files open correctly from the admin panel links.

Single Login & Access Control: Confirm that a single login screen correctly authenticates and separates user permissions, routing admins to the protected dashboard and blocking unauthorized URL access.

Admin Panel & Filters: Test the Name and Class search filters to ensure the student table updates instantly. Verify that admin edits keep Name and Email strictly locked while allowing other updates and deletions.

Code Structure & Reliability: Review code readability, architecture separation, and deployment ease (e.g., SQL file included). For paper submissions, verify clear step-by-step data flow logic
